The aim of this research was to investigate the influence of the nanostructured hydroxyapatite (NHAP) and Nano-sized titanium dioxide (NTiO$_2$) on dispersion in an adhesive mainly containing monomers of Dipenta erythritol penta-acrylate monophosphate (PENTA) and Urethane dimethacrylate (UDMA), also determine the aesthetic and mechanical properties of the coating solution. From different powders combinations, NHAP 75%W-NTiO$_2$ %25W with an average length of ~20 µm, at (10wt %) into the dental adhesive, manifested the most aesthetic appearance. Scanning/Transmission electron microscopy (SEM), (TEM) images showed that nano sized HAP/NTiO$_2$ mixed by the process of high-energy achieve the powders homogenization with a uniform dispersion. Nanoindentation studios and atomic force microscopy AFM developed the enhancement of mechanical properties such as, hardness H, elastic modulus E and scratching resistance on the enriched adhesive respect to the pure adhesive. In summary, the enrichment of methacrylate co-monomers adhesives PENTA/UDMA with mixtures of hydroxyapatite and titanium dioxide nanostructures may be considerate as a mechanical toughened, also a god option to modified shade qualities for dental aesthetic applications.
